1 Introduction

In this project, we implemented essential components of a 4-bit Arithmetic Logic Unit (ALU). First, we coded 4-bit binary logic functions, including AND, NAND, OR, NOR, XOR, XNOR, and NOT, as well as a 2x4-bit input/output shifter. We then implemented 4-bit arithmetic operations such as addition, subtraction, multiplication, and division, integrating carry-in and carry-out circuits for extended accuracy. We included an extra 4-bit output for multiplication and division remainders.

Next, we tested each circuit's functionality to ensure expected behavior, followed by generating simulation waveforms to visually confirm the ALU's performance. Finally, we compiled our work and observations into a comprehensive report, which summarizes the methods, results, and key insights gained from the project.

2 2x4 Shift Circuit

The 2x4 shift circuit takes a 4-bit input and shifts the bits left or right by up to two positions, depending on the control signal. Each shift moves the bits in the input to adjacent positions, and the vacant bits are filled with zeros. Shifting by one or two positions allows for additional flexibility in data manipulation, making the circuit versatile in operations where both single and double shifts are required.

2.1 Shift Circuit Verilog Code

```
'timescale 1ns / 1ps
3 module shift_tb;
      // Inputs
      reg [3:0] A;
      reg [1:0] amt;
      reg dir;
      // Outputs
10
      wire [3:0] Y;
12
      // Instantiate the shifter module
      shift_gate uut (
14
           .A(A),
15
           .amt(amt),
16
           .dir(dir),
17
```

```
. Y (Y)
      );
19
20
      initial begin
          // Open a file for waveform output
22
          $dumpfile("shift_tb.vcd");
23
          $dumpvars(0, shift_tb);
24
25
          // Test 1: No shift
26
          A = 4'b1010; // Input: 10
          amt = 2'b00; // Shift amount: 0
28
          dir = 1'b0;
                        // Direction: left
          #10;
30
31
          // Test 2: Left shift by 1
32
          amt = 2'b01; // Shift amount: 1
33
          dir = 1'b0; // Direction: left
34
          #10;
35
          // Test 3: Left shift by 2
37
          amt = 2'b10; // Shift amount: 2
38
          dir = 1'b0; // Direction: left
39
          #10;
40
41
          // Test 4: Right shift by 1
42
          amt = 2'b01;  // Shift amount: 1
43
          dir = 1'b1; // Direction: right
          #10;
45
46
          // Test 5: Right shift by 2
47
          amt = 2'b10; // Shift amount: 2
48
          dir = 1'b1; // Direction: right
49
          #10;
51
          // Test 6: Edge case - All zeros
52
          A = 4, b0000; // Input: 0
53
          amt = 2'b10; // Shift amount: 2
54
          dir = 1'b0; // Direction: left
55
          #10;
57
          // End simulation
58
          $finish;
      end
```

```
61 62 endmodule
```

To test the Shift circuit we have created 3 input registers, and 1 output. Input A is 4bits, being the input that we want to shift, next input, amt, is 2 bits, being the amount that we want to shift A by, and the last input, dir, is the direction we want to shift, being 0 for left and 1 for right. It will then output the resulting shifted bits into Y, and we will know if its working correctly if Y is a shifted version of A in the direction and the amount specified.

```
'timescale 1ns / 1ps
  module shift_tb;
      // Inputs
      reg [3:0] A;
6
      reg [1:0] amt;
      reg dir;
      // Outputs
      wire [3:0] Y;
      // Instantiate the shifter module
13
      shift_gate uut (
14
          .A(A),
15
           .amt(amt),
16
           .dir(dir),
17
           . Y (Y)
18
19
      );
20
      initial begin
          // Open a file for waveform output
          $dumpfile("shift_tb.vcd");
23
          $dumpvars(0, shift_tb);
24
25
          // Test 1: No shift
26
          A = 4'b1010; // Input: 10
          amt = 2'b00; // Shift amount: 0
          dir = 1'b0;
                        // Direction: left
29
          #10;
30
31
          // Test 2: Left shift by 1
32
          amt = 2'b01; // Shift amount: 1
33
          dir = 1'b0; // Direction: left
34
```

```
#10;
36
          // Test 3: Left shift by 2
          amt = 2'b10; // Shift amount: 2
                         // Direction: left
          dir = 1'b0;
30
          #10;
40
          // Test 4: Right shift by 1
42
          amt = 2'b01; // Shift amount: 1
43
                         // Direction: right
          dir = 1'b1;
          #10;
          // Test 5: Right shift by 2
          amt = 2'b10; // Shift amount: 2
48
          dir = 1'b1;
                         // Direction: right
49
          #10;
51
          // Test 6: Edge case - All zeros
52
          A = 4'b0000; // Input: 0
53
          amt = 2'b10; // Shift amount: 2
54
                         // Direction: left
          dir = 1'b0;
55
          #10;
57
          // End simulation
58
          $finish;
59
      end
60
62 endmodule
```

2.2 Shift Circuit Waveforms

At 10 ns, we can see that A is 1010, amt is 01 (1), and dir is 0 (left), so the output Y is 0100.

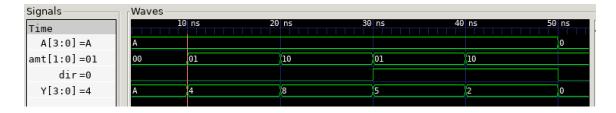

Figure 1: Shift Circuit with marker at 10ns

At 20 ns, we can see that A is 1010, amt is 10(2), and dir is 0 (left), so the output Y is 1000.

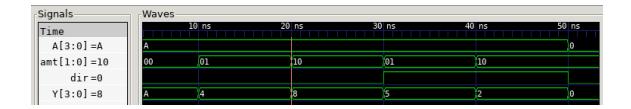

Figure 2: Shift Circuit with marker at 20ns

At 30 ns, we can see that A is 1010, amt is 01 (1), and dir is 1 (right), so the output Y is 0101.

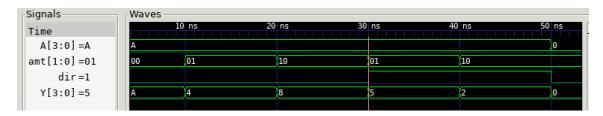

Figure 3: Shift Circuit with marker at 30ns

3 Not Circuit

The Not circuit takes one input A, with an output Y. This will output a 0 if A is a 1, and will output 1 if A is a 0.

3.1 Not Circuit Verilog Code

To test the Not circuit, we have created one register A, as well as a wire Y. This way we are able to take each input for A and test output for A=0 and A=1. We'll know if this is working correctly if Y returns 1 for the test where A is 0 and Y returns 0 when A is 1.

```
'timescale 1ns / 1ns
  'include "not_gate.v"
  module not_tb;
6 reg [3:0] A;
7 wire [3:0] Y;
9 not_gate uut(Y, A);
  initial begin
11
12
      $dumpfile("not_tb.vcd");//holds output waveform
13
      $dumpvars(0, not_tb);
14
15
           A = 4,00000; #10;
           A = 4'b1111; #10;
17
           A = 4'b1010; #10;
18
           A = 4,00101; #10;
20
      $display("Testing not");
21
23 end
24
25 endmodule
```

3.2 Not Circuit Waveform

At 0 ns, we can see that A is the 0h(0000), so the output Y is Fh(1111).

Figure 4: Not Circuit with marker at 0ns

At 20 ns, A becomes the Ah(1010), so Y becomes the 5h(0101).

Figure 5: Not Circuit with marker at 20ns

At 40 ns, A becomes the 5h(0101), so Y becomes the hex value Ah(1010).

Figure 6: Not Circuit with marker at 40ns

4 And Circuit

The And circuit takes two 4-bit inputs A and B, with a 4-bit output Y. A and B will undergo the bitwise And operation, and the result will be output to Y.

4.1 And Circuit Verilog Code

```
ifindef AND_GATE_V
define AND_GATE_V

module and_gate (Y, A, B);
output [3:0] Y;
input [3:0] A, B;
assign Y = A & B;
endmodule

'endif
```

To test the And circuit, we have created two registers A and B, as well as a wire Y. We then create a for loop to produce all 16 possible values for A and B. We will know that our And circuit is behaving as expected if Y produces correct values for all combinations of A and B. For example, if A=0001 and B=0001, the expected result for Y is 0001.

```
1 'timescale 1ns / 1ns
2 'include "and_gate.v"
3
4 module and_tb;
5
6    reg [3:0] A, B;
7    wire [3:0] Y;
8
9    and_gate uut(Y, A, B);
10
```

```
integer i, j;
12
      initial begin
13
          $dumpfile("and_tb.vcd");\
          $dumpvars(0, and_tb);
15
16
          // Loop through all 16 possible values of A and B
17
          for (i = 0; i < 16; i = i + 1) begin
18
               for (j = 0; j < 16; j = j + 1) begin
19
                   A = i;
20
                   B = j;
22
                   #10;
                   $display("A = %b, B = %b, Y = %b", A, B, Y); // Display A,
23
       B, and Y
               end
24
          end
26
          $display("All combinations tested");
27
          $finish;
28
      end
29
30
31 endmodule
```

4.2 And Circuit Waveform

At 1ns, A and B are both 0000, so Y is also 0000

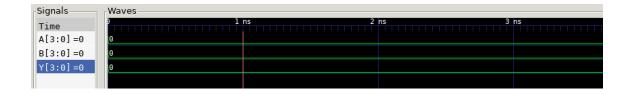

Figure 7: And Circuit with marker at 1ns

At 500ns, A=0011 and B=0010, so Y=0010

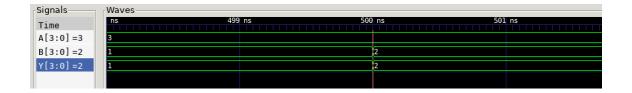

Figure 8: And Circuit with marker at 500ns

At 2550ns, A and B are both F (1111), so Y is also F (1111).

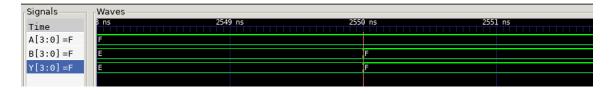

Figure 9: And Circuit with marker at 2550ns

5 Nand Circuit

The Nand circuit takes two 4-bit inputs A and B, with a 4-bit output Y. A and B will undergo the bitwise Nand operation, and the result will be output to Y. "

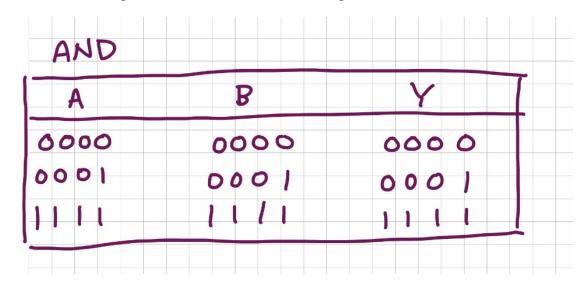

Figure 10: And truth table and gate

5.1 Nanad Circuit Verilog Code

```
'ifindef NAND_GATE_V

'define NAND_GATE_V

module nand_gate (Y, A, B);

output [3:0] Y;

input [3:0] A, B;

assign Y = ~(A & B);

endmodule

'endif

'endif

'endif

'endif

'define NAND_GATE_V

assign Y = A & B);

'endif

'e
```

To test the Nand circuit, we have created two registers A and B, as well as a wire Y. We then create a for loop to produce all 16 possible values for A and B. We will know that our Nand circuit is behaving as expected if Y produces correct values for all combinations of A and B. For example, if A=0001 and B=0001, the expected result for Y is 1110.

```
1 'timescale 1ns / 1ns
'include "nand_gate.v"
4 module nand_tb;
6 reg [3:0] A, B;
7 wire [3:0] Y;
9 nand_gate uut(Y, A, B);
integer i, j;
13 initial begin
      $dumpfile("nand_tb.vcd");
15
      $dumpvars(0, nand_tb);
16
17
      // Loop through all 16 possible values of A and B
18
      for (i = 0; i < 16; i = i + 1) begin
19
          for (j = 0; j < 16; j = j + 1) begin
              A = i;
21
              B = j;
22
23
              display("A = \%b, B = \%b, Y = \%b", A, B, Y); // Display A, B,
24
      and Y
```

```
26    end
27
28    $display("All combinations tested");
29    $finish;
30 end
31
32 endmodule
```

5.2 Nand Circuit Waveform

At 1ns, A and B are both 0000, so Y is F (1111).

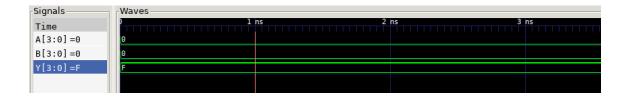

Figure 11: Nand Circuit with marker at 1ns

At 500ns, A=0011 and B=0010, so Y=D (1101)

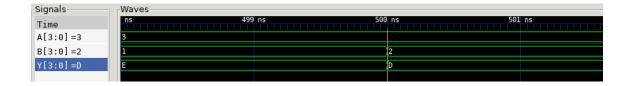

Figure 12: Nand Circuit with marker at 500ns

At 2500ns, A and B are both F (1111), so Y is 0000.

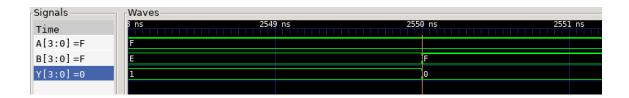

Figure 13: Nand Circuit with marker at 560ns

6 Or Circuit

The Or circuit takes two 4-bit inputs A and B, and has a 4-bit output Y. Each bit of Y is the result of a bitwise OR operation applied between corresponding bits in A and B.

6.1 Or Circuit Verilog Code

```
'ifndef OR_GATE_V
'define OR_GATE_V

module or_gate (Y, A, B);
   output [3:0] Y;
   input [3:0] A, B;
   assign Y = A | B;
endmodule

'endif
```

To test the Or circuit, we have created two registers A and B, as well as a wire Y. We then create a for loop to produce all 16 possible values for A and B. We will know that our And circuit is behaving as expected if Y produces correct values for all combinations of A and B.

```
1 'timescale 1ns / 1ns
'include "or_gate.v"
4 module or_tb;
      reg [3:0] A, B;
      wire [3:0] Y;
      or_gate uut(Y, A, B);
10
      integer i, j;
11
12
      initial begin
13
          $dumpfile("or_tb.vcd");
          $dumpvars(0, or_tb);
15
16
          // Loop through all 16 possible values of A and B
17
          for (i = 0; i < 16; i = i + 1) begin
18
               for (j = 0; j < 16; j = j + 1) begin
19
                   A = i;
```

6.2 Or Circuit Waveform

At 160 ns, A is 1 (0001) and B is 0 (0000), so Y is 1 (0001).

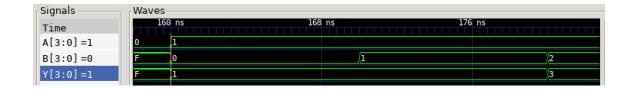

Figure 14: Nor Circuit with marker at 160ns

At 1650 ns, A is A (1010) and B is 5 (0101), so Y is now F (1111).

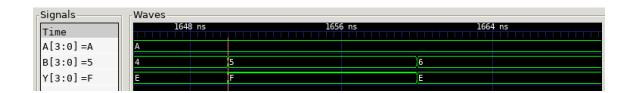

Figure 15: Nor Circuit with marker at 1650ns

At 2400 ns, A is F (1111) and B is 0 (0000), so Y is now F (1111).

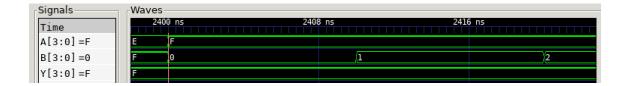

Figure 16: Nor Circuit with marker at 2400ns

7 Nor Circuit

The Or circuit takes two 4-bit inputs A and B, and has a 4-bit output Y. Each bit of Y is the result of the opposite of a bitwise OR operation applied between corresponding bits in A and B.

7.1 Nor Circuit Verilog Code

```
'ifindef NOR_GATE_V
'define NOR_GATE_V

module nor_gate (Y, A, B);

output [3:0] Y;

input [3:0] A, B;

assign Y = ~(A | B);

endmodule

'endif
```

To test the Nor circuit, we have created two registers A and B, as well as a wire Y. We then create a for loop to produce all 16 possible values for A and B. We will know that our And circuit is behaving as expected if Y produces correct values for all combinations of A and B.

```
1 'timescale 1ns / 1ns
2 'include "nor_gate.v"
3
4 module nor_tb;
5
6    reg [3:0] A, B;
7    wire [3:0] Y;
8
9    nor_gate uut(Y, A, B);
10
```

```
integer i, j;
12
      initial begin
13
          $dumpfile("nor_tb.vcd");
          $dumpvars(0, nor_tb);
15
16
          // Loop through all 16 possible values of A and B
17
          for (i = 0; i < 16; i = i + 1) begin
18
               for (j = 0; j < 16; j = j + 1) begin
19
                   A = i;
20
                   B = j;
22
                   #10;
                   $display("A = %b, B = %b, Y = %b", A, B, Y); // Display A,
23
       B, and Y
               end
24
           end
26
           $display("All combinations tested");
27
          $finish;
      end
29
30
31 endmodule
```

7.2 Nor Circuit Waveform

At Ons, A and B are both 0000, so Y is F (1111).

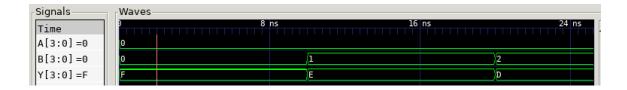

Figure 17: Nor Circuit with marker at 0ns

At 2400ns, A is F (1111) and B is 0 (0000), so Y is 0 (0000).

Figure 19: Nor Circuit with marker at 1600ns

8 Xor Circuit

The Xor circuit takes two 4-bit inputs A and B, with a 4-bit output Y. A and B will undergo the bitwise Xor operation, and the result will be output to Y.

To test the Xor circuit, we have created two registers A and B, as well as a wire Y. We then create a for loop to produce all 16 possible values for A and B. We will know that our Xor circuit is behaving as expected if Y produces correct values for all combinations of A and B. For example, if A=1010 and B=1101, the expected result for Y is 0111.

```
1 'timescale 1ns / 1ns
2 'include "xor_gate.v"
3
```

```
4 module xor_tb;
      reg [3:0] A, B;
6
      wire [3:0] Y;
      xor_gate uut(Y, A, B);
10
      integer i, j;
11
12
      initial begin
13
          $dumpfile("xor_tb.vcd");
14
          $dumpvars(0, xor_tb);
15
          // Loop through all 16 possible values of A and B \,
17
          for (i = 0; i < 16; i = i + 1) begin
18
               for (j = 0; j < 16; j = j + 1) begin
                   A = i;
20
                   B = j;
21
                   #10;
22
                   $display("A = %b, B = %b, Y = %b", A, B, Y); // Display A,
       B, and Y
               end
          end
25
26
          $display("All combinations tested");
27
          $finish;

8.1 Xor Circuit Waveform

At 1ns, A and B are both 0000, so Y is also 0000.

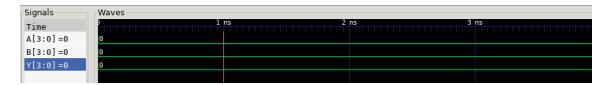

Figure 20: Xor Circuit with marker at 1ns

At 500ns, A=0011 and B=0010, so Y=0001.

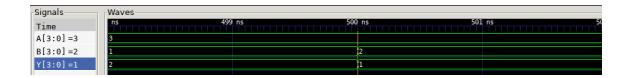

Figure 21: Xor Circuit with marker at 500ns

At 2500ns, A and B are both F, so Y=0000.

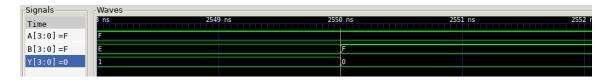

Figure 22: Xor Circuit with marker at 2500ns

9 XNor Circuit

The Xnor circuit takes two 4-bit inputs A and B, with a 4-bit output Y. A and B will undergo the bitwise Xnor operation, and the result will be output to Y.

```
'ifindef xnor_GATE_V

'define xnor_GATE_V

module xnor_gate (Y, A, B);

output [3:0] Y; // 4-bit output

input [3:0] A; // 4-bit input

input [3:0] B; // 4-bit input

assign Y = ~(A ^ B);

endmodule

'endif

'endif
```

To test the Xnor circuit, we have created two registers A and B, as well as a wire Y. We give the circuit some test cases to test its validity. We will know that our Xnor circuit is behaving as expected if Y produces correct values for all combinations of A and B. For example, if A = 1010 and B = 1101, the expected result for Y is 1000.

```
1 'timescale 1ns / 1ns
2 'include "xnor_gate.v"
3
```

```
4 module xnor_tb;
6 reg [3:0] A;
7 reg [3:0]B;
8 wire [3:0] Y;
10 xnor_gate uut(
      .Y(Y),
      .A(A),
12
      .B(B));
13
integer i; // Loop variable
16 initial begin
17
      $dumpfile("xnor_tb.vcd");//holds output waveform
18
      $dumpvars(0, xnor_tb);
          // Apply test cases
20
          A = 4,00000; B = 4,00000; #10;
21
          A = 4,00000; B = 4,01111; #10;
22
           A = 4'b1010; B = 4'b0101; #10;
          A = 4'b1100; B = 4'b1010; #10;
24
           A = 4'b1111; B = 4'b1111; #10;
          A = 4'b0110; B = 4'b0110; #10;
26
          A = 4'b1001; B = 4'b1001; #10;
27
          A = 4'b1101; B = 4'b0111; #10;
29
30
      $display("Testing xnor");
31
32
33 end
34
35 endmodule
```

9.1 Xnor Circuit Waveform

At 1ns, A and B are both 0h (0000), so Y is Fh(0000).

Figure 23: Xnor Circuit with marker at 1ns

At 20ns, A = Ah (1010) and B = 5h(0101), so Y = 0h (0000).

Figure 25: Xor Circuit with marker at 2500ns

10 Addition Circuit

The Addition circuit takes two 4-bit inputs A and B along with a 1-bit carry in to extend the output range from 15 to 31. The circuit's outputs include a 4-bit output called Sum, along with a 1-bit carry out to accommodate the extended range. The has an intermediary 5-bit variable, full sum, which is used to extract carry out and partial sum. First the full sum is found by adding A, B, and carry in. Then, Sum is assigned to the 4 lower bits of full sum. Then, carry out is assigned to the 5th bit of full sum.

```
output [3:0] Sum,
                              // 4-bit sum output
      output carry_out
                              // 1-bit carry out
10 );
11
      wire [4:0] full_sum; // 5-bit sum to accommodate carry-out
12
13
      // Perform the addition with carry_in
14
      assign full_sum = A + B + carry_in;
15
16
      // Assign the lower 4 bits of the sum to the Sum output
      assign Sum = full_sum[3:0];
18
19
      // The 5th bit is the carry_out
20
      assign carry_out = full_sum[4];
21
23 endmodule
24
25 'endif
```

To test the Addition circuit, we have created two registers A and B, a register carry in, a wire Sum, and a wire carry out. We then perform 5 tests with A, B, and carry in at various values. We will know that the Addition circuit is working as expected if carry out plus Sum produces correct results for every combination of A, B, and carry in that we have tested. For example, if A is 1000, B is 1000, and carry in is 1, then the expected result: Sum is 0001, carry out is 1 for a decimal value of 17.

```
timescale 1ns / 1ns
'include "addition.v" // Include the addition module
4 module addition_tb;
      reg [3:0] A, B;
                          // 4-bit inputs
      reg carry_in;
                           // 1-bit carry in
      wire [3:0] Sum;
                           // 4-bit sum output
      wire carry_out;
                           // 1-bit carry out
10
      // Instantiate the addition module
      addition uut (
          .A(A),
13
          .B(B),
14
          .carry_in(carry_in),
15
16
          .Sum(Sum),
          . carry_out(carry_out)
17
```

```
);
19

```

10.1 Addition Circuit Waveform

At 2ns, A is 1 and B is 2, so Sum is 3 with carry in and carry out at 0.

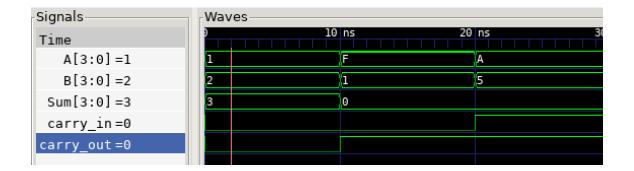

Figure 26: Addition Circuit with marker at 2ns

At 20ns, A is A(1010) and B is 5(0101), so Sum is F(1111) with carry in and carry out at 0.

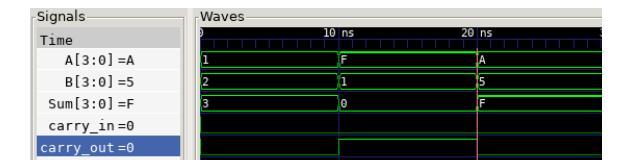

Figure 27: Addition Circuit with marker at 20ns

At 30ns, A and B are both 8(1000), so Sum is 1 with carry in and carry out at 1, resulting in a decimal value of 17.

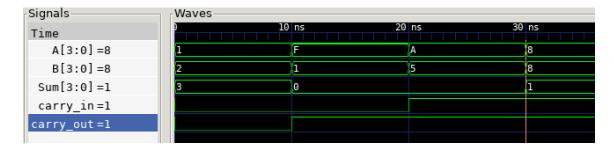

Figure 28: Addition Circuit with marker at 30ns

11 Multiplication Circuit

The Multiplication circuit takes two 4-bit inputs A and B, and produces two 4-bit outputs, product low and product high, representing the high and low 4 bits of the product of A and B. The circuit has an intermediary 8-bit variable, full product, which is used to extract the low and high 4 bits of the product. First, full product is assigned to the product of A and B. Then, product low is assigned the first 4 bits of full product. Then, product high is assigned the last 4 bits of full product.

```
'ifndef MULTIPLICATION_V

'define MULTIPLICATION_V

module multiplier_4bit (
   input [3:0] A, B,
   output [3:0] product_low, // Lower 4 bits of the product
   output [3:0] product_high // Upper 4 bits of the product
```

```
8 );
9  wire [7:0] full_product;  // 8-bit wire to hold the full product
10
11  assign full_product = A * B;
12  assign product_low = full_product[3:0];  // Lower 4 bits
13  assign product_high = full_product[7:4];  // Upper 4 bits
14 endmodule
15
16 'endif
```

To test the Multiplication circuit, we have created two registers A and B, and two wires product low and product high. We then perform 5 tests with A and B at various values. We will know that the Multiplication circuit is working as expected if product low, product high produces correct results for every combination of A times B that we have tested. For example, if A is 1111 and B is 1111, then the expected result: product high is 1110, product low is 0001 for a decimal value of 225.

```
'timescale 1ns / 1ns
  'include "multiplication.v"
4 module multiplication_tb;
      reg [3:0] A, B;
      wire [3:0] product_low;
      wire [3:0] product_high;
      multiplier_4bit uut (
          .A(A),
11
          .B(B),
          .product_low(product_low),
13
          .product_high(product_high)
14
      );
15
      initial begin
17
          $dumpfile("multiplication_tb.vcd");
18
          $dumpvars(0, multiplication_tb);
20
          A = 4'b0010; B = 4'b0011; #10;
21
          $display("A = %b, B = %b, product_low = %b, product_high = %b", A,
22
     B, product_low, product_high);
23
          A = 4'b0101; B = 4'b0101; #10;
24
```

```
$display("A = %b, B = %b, product_low = %b, product_high = %b", A,
     B, product_low, product_high);
26
          A = 4'b0110; B = 4'b0011; #10;
          $display("A = %b, B = %b, product_low = %b, product_high = %b", A,
28
     B, product_low, product_high);
29
          A = 4'b1001; B = 4'b0100; #10;
30
          $display("A = %b, B = %b, product_low = %b, product_high = %b", A,
31
     B, product_low, product_high);

          A = 4'b1111; B = 4'b1111; #10;
33
          $display("A = %b, B = %b, product_low = %b, product_high = %b", A,
34
     B, product_low, product_high);
35
          $display("Selected test cases completed");
          $finish;
37
      end
38
40 endmodule
```

11.1 Multiplication Circuit Waveform

At 2ns, A is 2 and B is 3, so product high is 0 and product low is 6.

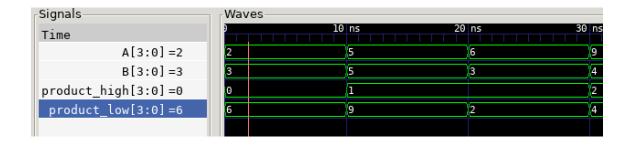

Figure 29: Multiplication Circuit with marker at 2ns

At 20ns, A is 6 and B is 3, so product upper is 0001 and product lower is 0010 for a decimal value of 18.

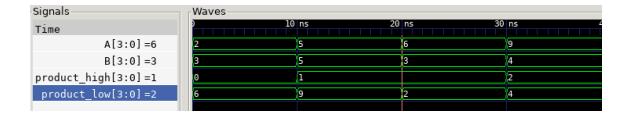

Figure 30: Multiplication Circuit with marker at 20ns

At 40ns, A and B are both F, so product upper is E and product lower is 0001 for a decimal value of 256.

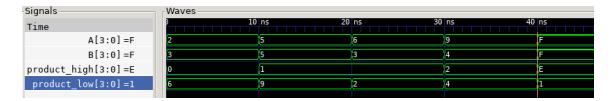

Figure 31: Multiplication Circuit with marker at 40ns

12 Subtraction Circuit

12.1 Subtraction Circuit Verilog Code

The Multiplication circuit takes two 4-bit inputs A and B, and produces one 4-bit output, Y with the difference of the two

```
ifindef SUBTRACTION_V
define SUBTRACTION_V

module subtraction (Y, A, B);
output [3:0] Y; // 4-bit output
input [3:0] A; // 4-bit input A
input [3:0] B; // 4-bit input B

assign Y = A - B; // Perform 4-bit subtraction

endmodule

endmodule

rendif
```

To test the Subtraction circuit, we have created two registers A and B and a wire Y for output. We then perform 5 tests with A and B at various values. We will know that the Subtraction circuit is working as expected if it produces correct results for every combination of A times B that we have tested. For example, if A is 1111 and B is 1111, then the expected result: Y is 0000

```
'timescale 1ns / 1ns
  'include "subtraction.v"
4 module subtraction_tb;
                        // 4-bit input A
      reg [3:0] A;
      reg [3:0] B;
                        // 4-bit input B
      wire [3:0] Y;
                        // 4-bit output Y (result of A - B)
      subtraction uut (Y, A, B);
10
      initial begin
          $dumpfile("subtraction_tb.vcd"); // Holds output waveform
13
          $dumpvars(0, subtraction_tb);
14
15
          // Test cases for 4-bit subtraction
16
          A = 4'b0001; B = 4'b0001; #10; // Expected Y: 0000
17
18
          A = 4'b1010; B = 4'b0011; #10; // Expected Y: 0111
          A = 4'b1100; B = 4'b0101; #10; // Expected Y: 1001
19
          A = 4'b1111; B = 4'b1110; #10; // Expected Y: 0001
20
          A = 4'b0101; B = 4'b1001; #10; // Expected Y: Overflow
21
22
          $display("Testing subtraction");
24
      end
25
26 endmodule
```

12.2 Subtraction Circuit Waveform

At 0ns, A is 1h (0001) and B is 1h (0001), so Y = 0h (0000)

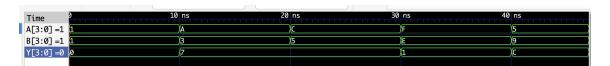

Figure 32: Subtraction Circuit with marker at Ons

At 0ns, A is Ch (1100) and B is 5h (0101), so Y = 7h (0111)

Figure 33: Subtraction Circuit with marker at 20ns

At 0ns, A is 5h (0101) and B is 9h (1001), so Y = Ch (1100)

Figure 34: Multiplication Circuit with marker at 40ns

13 Division Circuit

The Division circuit takes two 4-bit inputs A and B, and produces two 4-bit outputs, quotient (Q) and remainder (R). The circuit first calculates how many times B can go into A, becoming Q, then it takes Q amount of B's away from A and the resulting number is R.

```
module division (
      input [3:0] dividend,
      input [3:0] divisor,
      output reg [3:0] quotient,
      output reg [3:0] remainder,
      output reg valid
7);
      reg [3:0] temp_dividend;
      reg [3:0] temp_quotient;
10
      integer i;
      always @(*) begin
13
          quotient = 4'b0000;
14
          remainder = 4'b0000;
15
          valid = 1,b0;
16
17
          if (divisor == 0) begin
```

```
valid = 1'b0;
               quotient = 4'b0000;
20
               remainder = dividend;
          end else begin
               temp_dividend = dividend;
23
               temp_quotient = 4'b0000;
24
               for (i = 3; i >= 0; i = i - 1) begin
26
                   temp_quotient = {temp_quotient[2:0], temp_dividend[3]};
27
                   temp_dividend = {temp_dividend[2:0], 1'b0};
29
                   //if (temp_quotient >= divisor) begin
30
                          temp_quotient = temp_quotient - divisor;
31
                          dividend[i:i] = 1'b1;
32
                   11
                          end
33
34
               end
               quotient = temp_quotient;
36
37
               remainder = dividend;
               valid = 1'b1;
38
          end
39
      end
41 endmodule
```

To test the Division circuit, we have created two registers A and B, and two wires quotient (Q) and remainder (R). We then perform 5 tests with A and B at various values. We will know that the Division circuit is working as expected if quotient and remainder produces correct results for every combination of A times B that we have tested.

```
'timescale 1ns / 1ps
3 module division_tb;

13.1 Multiplication Circuit Waveform

At 0ns, A is 0 and B is 1, so the quotient is 0 and the remainder is also 0.

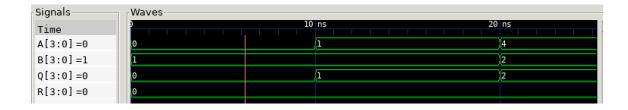

Figure 35: Division Circuit with marker at 0ns

At 20ns, A is 4 and B is 2, so the quotient is 2 and the remainder is 0.

Signals	- Waves
Time	20 ns 30 ns
A[3:0] =4	1 4 7
B[3:0]=2	1 2 4
Q[3:0] =2	1 2 1
R[3:0]=0	0 3

Figure 36: Division Circuit with marker at 20ns

At 30ns, A is 7 and B is 4, so the quotient is 1 and the remainder is 3.

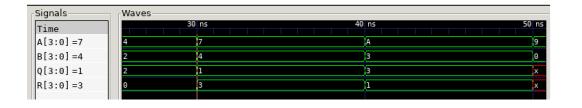

Figure 37: Division Circuit with marker at 30ns

14 Conclusion

This project introduced the design and testing of a basic 4-bit Arithmetic Logic Unit (ALU). We coded essential logic functions like AND, OR, and NOT, along with shifting operations, which are crucial for handling binary data. We also developed basic arithmetic operations—addition, subtraction, multiplication, and division—which included handling carries and remainders to ensure accurate results.

Testing the circuits and generating waveforms confirmed that our ALU worked correctly across different inputs. This process highlighted the importance of both accuracy in coding and thorough testing. Overall, the project has been valuable for understanding digital circuits and the structure of an ALU, preparing us for more advanced digital logic design.
